## Problem & Insights

Hospital and insurer systems don't connect, forcing patients to use multiple apps yet still lack real-time cost or approval visibility. Staff re-enter data manually, records stay siloed, and communication remains slow — causing duplication, delays, and patient anxiety.

## Competitor Gap

Insurer apps (e.g. Medibank, Bupa) handle policies and claims but don't link with hospitals.
Hospital systems (e.g. Epic, TeleTracking) manage flow but ignore insurance.
Telehealth tools (e.g. Teladoc, Healthdirect) improve access but not cost clarity.
No platform unifies AI pre-diagnosis, booking, insurance, and records.

## Concept

Insurance Handshake — an integrated platform linking hospitals and insurers.
AI pre-diagnosis → smart booking → live cost visibility → shared medical record.
A unified, stress-free healthcare journey for both patients and staff.

## Scenario

The patient struggles to understand her insurance coverage and out-of-pocket costs.
Delays and unclear approvals make her anxious and hesitant to proceed with treatment.

## Guiding HMW Question

How might we make eligibility, pre-authorisation and out-of-pocket costs transparent in real time, so patients can plan with confidence?
This question captures the core of the problem—lack of financial clarity—and guided our design decisions.

## Design Evolution

Our design progresses through iterations from Wireframe → Mid-Fi → Hi-Fi Prototype.

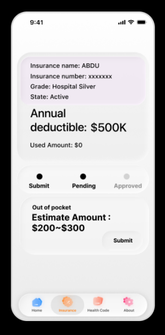

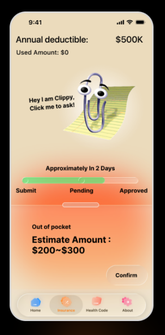

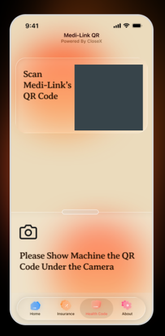

Initial version issues (Mid-Fi): Too much text on the page, confusing information hierarchy, and unintuitive buttons.

Improvement direction: Based on test feedback, reorganize the information into information summary cards (Smart Cards) .

UI Iteration (Hi-Fi):
- Highlight key information locations to enhance readability;
- Add explanatory text to QR codes to clarify usage scenarios;
- Use Auto Layout to achieve adaptive layout, improving consistency across devices;
- Adjust color schemes and font hierarchy to unify the visual style.

## Super Intelligent Powered Health App

| Mid-fi | | High-fi | |
|---|---|---|---|
|  | Overloaded text, unclear hierarchy, weak progress feedback |  | Simplified layout and grouped information by priority. |
| | | | Switched to warm orange tones for a calm, friendly feel. |
|  | Too empty — users unsure what to do. |  | Added guiding text and visual focus on QR area. |
| | | | Animation: Breathing zoom effect to convey vitality and hospital atmosphere. |

**Our main improvements originated from user feedback, Peer Review, and Expert Feedback.**

- "But I feel like it was a bit text-heavy. I think you could have more icons if it's for everyone."
- Reduce the information structure and add icons and summary cards

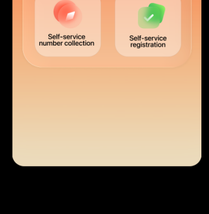

- "There are a lot of information on one page and I don't have enough time to actually see all the things because there is no priority for the visual elements."
- Reconstruct the visual hierarchy and layout ratio

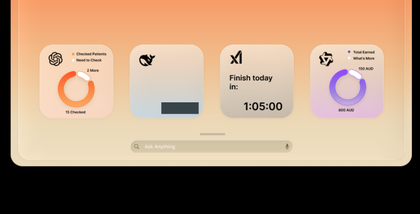

Peer Review :
- "QR code - not sure what it's used for"
- Add prompt text under the button "Scan for Doctor Access"

Expert Feedback :
- "Use real data, unified UI, independent elderly mode"
- Increase medical sample data, redesign the elderly mode as an independent interface

## Omni-channel

The future health system achieves seamless integration between devices and various links, ensuring that patients, doctors, and insurance companies can maintain contact through a continuous platform.

## Accessibility & Inclusion

In the design process, we have fully taken into account the needs of users of different ages and abilities:
- Senior Mode: A separate entry point, with enlarged fonts, increased button spacing, and enabled voice narration;
- Multimodal interaction: Voice input + touch operation + automatic feedback, enhancing the experience for users with visual or mobility impairments;

## Reflection & Future Work

Project Achievements:
- Learned how to convert user research and test feedback into specific design decisions;
- Practiced the complete interaction iteration from sketches to high-fidelity prototypes;
- Understood the design value of "transparency, trust and accessibility" in the medical field.

Weaknesses:
- The current system mainly focuses on the patient and doctor ends, while the interaction with the insurance end is still relatively static;
- The voice assistant function has not achieved natural semantic reasoning;
- The medical data display on some pages is still relatively complex.

Future Plans:
- Integrate more real-time insurance APIs to achieve automatic reimbursement confirmation;
- Optimize voice recognition and multilingual support;
- Explore AI prediction functions to provide personalized health advice for patients;
- Conduct larger-scale user tests to verify the usability of the system in real medical scenarios.
