01 / PRIMARY PROJECT · LONGEST INVOLVEMENT

Making field work connect across roles.

Fire Equipment Management Platform

CONTEXT
5-person team · 4-month delivery phase

STAGE
Delivery and ongoing iteration

MY FOCUS
Requirements · Interaction direction · Handoff

My longest project involvement shows how I carry context from business requirements into interaction decisions, testing and delivery. I turn ambiguous needs into a defined next step the team can review and test.

The challenge

A site owner, field inspector, installation team and administrator see different parts of the same work. An unclear entry point, mismatched task status or ambiguous completion step can interrupt the handoff between them.

The design problem extends beyond individual screens: it includes the business object being managed, the person responsible and the evidence of the next action.

My contribution

I prepared overseas requirements discussions, clarified site and role boundaries, reviewed cross-app interactions and helped turn observed issues into prioritised fixes and checks.

I worked with product, backend and hardware colleagues. Engineering teammates and AI-assisted workflows supported implementation while I focused on requirements, interaction review and delivery coordination.

Four surfaces, one connected service

01
Site owner
Manage sites
Inspect equipment
Request support

02
Field inspector
Receive assignments
Check evidence
Submit conclusions

03
Installation team
Install equipment
Review status
Handle field work

04
Administrator
Coordinate work
Review certificates
Handle alert cases

Anonymised role overview, reconstructed for this case study.

Delivery stage. The work progressed through Android build handoffs and continued workflow refinement.

02 / REQUIREMENTS

Start with the right unit of work.

Stakeholder clarification shaped the site model and the division of responsibilities.

What needed clarification

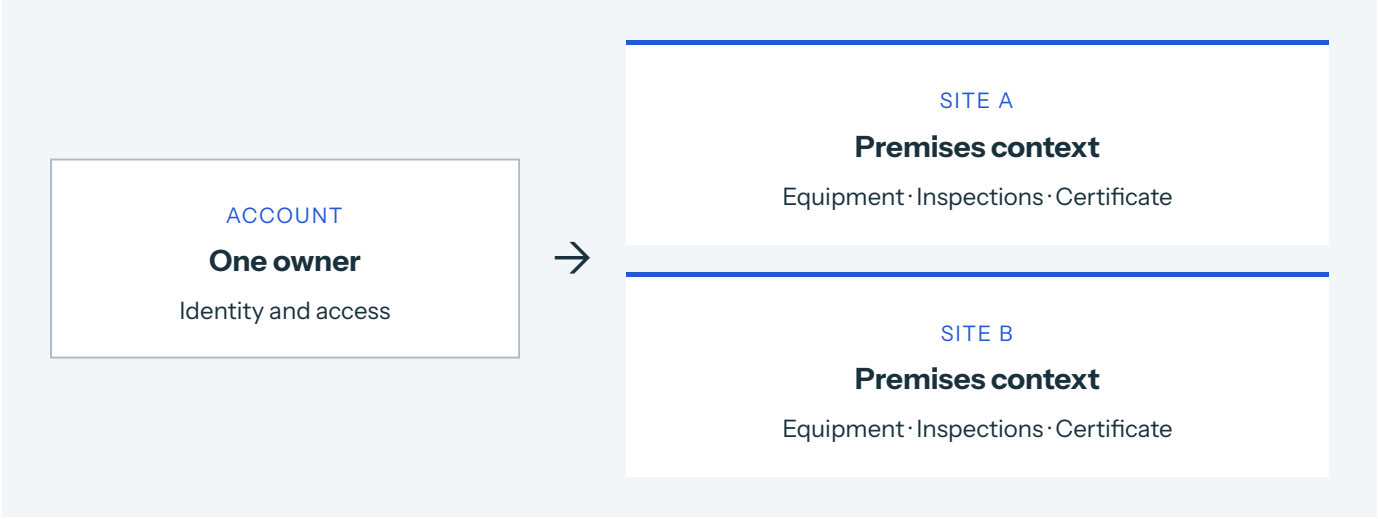

Before an overseas discussion, I identified questions about what a certificate covered, how related charges were separated, who installed smoke detectors and which interface should hold those responsibilities.

I requested an English discussion guide, then supplied the meeting transcript for follow-up synthesis. The stakeholder input helped distinguish site certification from the connected-device service.

What I took forward

I proposed allowing an owner to manage multiple sites. Later, I clarified that a site's personal or organisational classification should not be duplicated as an account type during registration.

This kept two concepts separate: who signs in and which places they manage. Installation responsibilities also needed their own operational surface rather than being placed indiscriminately in the owner or inspector app.

Reconstructed conceptual model with fictional sites.

THE PRODUCT DECISION

Put each choice where it belongs.

Account registration should establish the person. Site management should establish the premises. Installation and inspection should follow their actual responsibilities.

03 / BUSINESS JOURNEY

Connect the work, then follow it through.

A broad service journey across site ownership, field work and administration.

I reviewed the platform as connected business journeys: establishing a site, coordinating work, and making the outcome visible to the next role.

ESTABLISH THE CONTEXT

Owner + site

Identify the premises and its equipment; understand the certificate or installation need.

↓

COORDINATE FIELD WORK

Installation

Request support, assign the relevant team and review installation progress.

Inspection

Assign a check, accept the task, complete field work and submit the conclusion.

↓

REVIEW + CONTINUE

Administrator + owner

Review the outcome, make the next status clear and continue with certification or follow-up work.

Anonymised business-level reconstruction. The installation and inspection paths show different roles, not one mandatory sequence.

Where I focused

I clarified what belonged to the account or site, questioned unreachable request paths, and reviewed whether a task could continue naturally after acceptance. I also reported when a completed field task still appeared open elsewhere.

A separate urgent journey

Routine inspection was not the same job as emergency response. Later requirements brought owner reports and device alerts into an admin coordination workflow, with location, contact and explicit incident-end feedback.

> **The product lesson.** A completed action on one screen is a handoff to another person. I used those handoffs to frame review, prioritisation and the next check with the team.

04 / INTERACTION DIRECTION

Keep the task moving.

Reviewing hierarchy, status and transitions across the mobile apps and admin console.

I tested and reviewed the interfaces as connected tasks, asking what an operator should understand, choose and see after each action.

01 Show the problem, not just a category.

I asked for specific status wording rather than a generic warning or non-compliance label, supported by a consistent severity colour. I also reviewed drawer details and redundant close controls in the admin interface.

Illustrative copy direction: ~~Warning~~ → **Expires within 30 days**

02 Accept a task, then continue doing it.

On the inspector app, I wanted the assignment itself to have visual priority. After acceptance, the flow should continue into inspection instead of bouncing the person back to the list and forcing another search.

Read assignment → Accept task → Continue inspection

03 Use a shared interaction language.

I requested alignment between the installation app and the existing owner/inspector apps, including navigation, refresh behaviour, input and feedback. Earlier testing identified missing back navigation, unclear completion feedback and card layouts with weak information hierarchy.

Make handoff understandable

I requested separate usage guides for all four surfaces, written around human actions rather than internal technical calls. I also asked for step-by-step test instructions with an explicit result record.

Work with engineering

I provided interaction direction, concrete observations, sequencing and review. Engineering and AI-assisted workflows translated these into shared specifications, implementation and checks.

Copy and task-flow examples reconstructed from the review direction.

05 / WORKFLOW REFINEMENT

An alert needs a clear next action.

Moving from signal presentation to an understandable dispatch workspace.

Revisit who actually responds

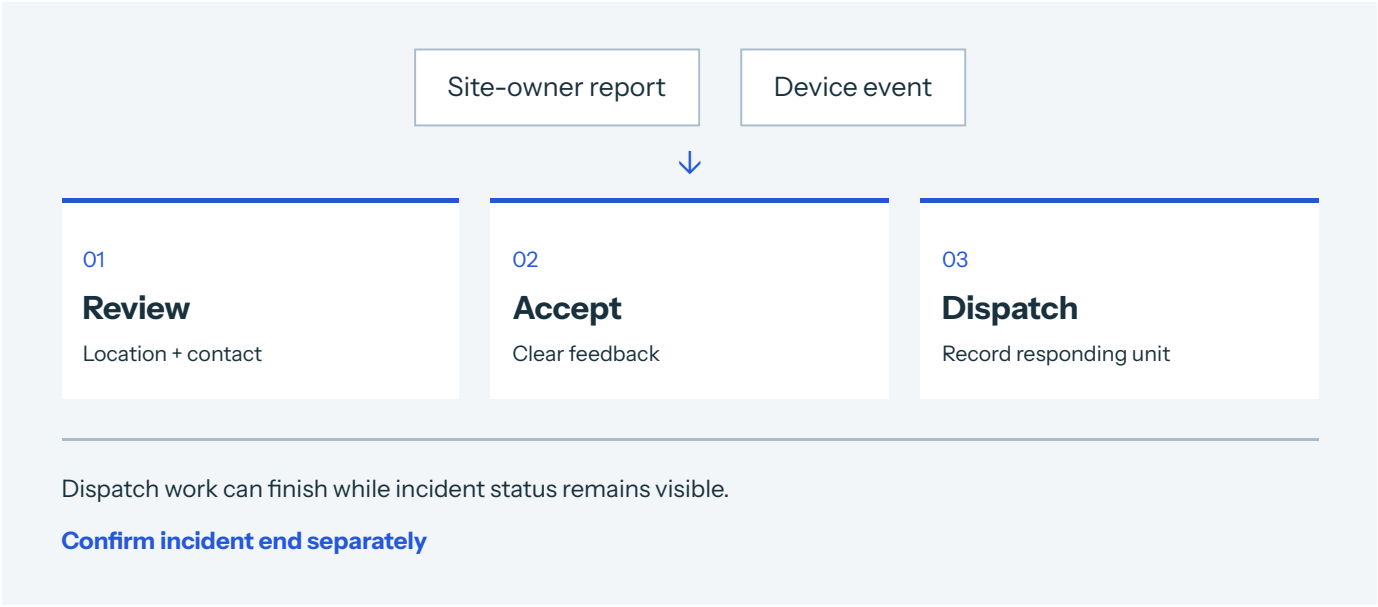

I raised the need for a site owner to report a fire and clarified that the inspector app was used for inspection staff, not every emergency responder. This moved emergency coordination towards the admin workspace.

I discussed location confirmation, accidental activation, responsible operators and contact information, while reviewing AI-assisted proposals for the case workflow and shared editing.

Let testing change the scope

After trying the flow, I found acceptance and completion unclear. I questioned the long reporting sequence because we had not yet established the real dispatcher's reporting needs.

I proposed a smaller first workflow centred on confirming the responding unit. I then asked how a dispatched alert would leave the map, exposing the difference between sending help and confirming that an incident had ended.

Anonymised workflow reconstruction based on the refined requirements.

The resulting direction

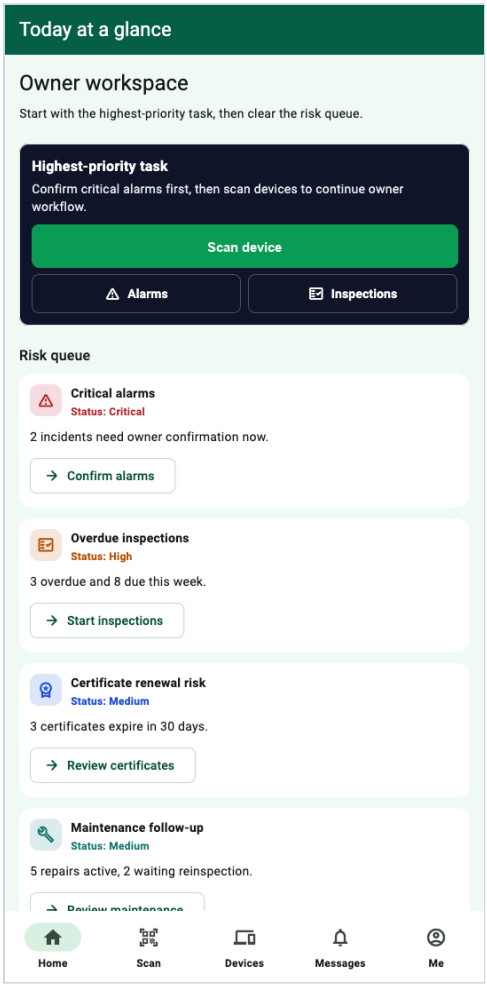

The subsequent team specification separated the dispatch queue from confirmation that an incident had ended. It retained site contacts, visible progress and accountable actions while reducing routine form filling. Device state and administrative case status remained distinct.

> **My role in the decision.** I challenged confusing transitions, narrowed the first scope and reviewed operational boundaries. AI and engineering contributed detailed case-state, editing and implementation solutions.

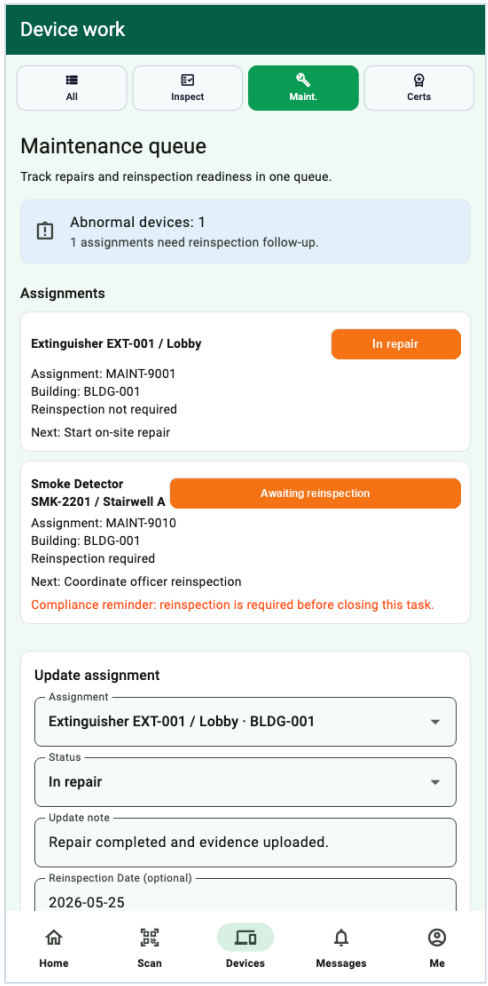

06 / APP INTERFACES

Clear priorities. Concrete next actions.

Existing app UI, captured in fixture mode with demonstration data.

Owner workspace: priority task and risk queue.

Maintenance: status, follow-up and next action.

What the interface makes tangible

The workspace brings priorities and next actions together. The maintenance queue separates repair progress from reinspection, with task status and a clear follow-up action.

My contribution in context

I reviewed task hierarchy, status wording, navigation consistency and completion feedback across the project. These are team-built interfaces, shown as concrete product context rather than a claim that I designed or coded every element.

Original project screenshots from existing Flutter UI fixture captures. Demonstration counts and identifiers; no production session or real-device operation. Screens shown are an existing documented version, not a claim about the latest release.

07 / ONGOING INVOLVEMENT

A project that kept evolving.

Continued involvement across changing requirements, build handoffs and operator feedback.

JUN	Clarify certificate scope, installation responsibilities and multi-site needs.
JUL	Review mobile consistency, operator guidance and end-to-end test steps.
AUG	Prioritise the smallest complete workflows and review cross-role interactions.
SEP	Coordinate a demonstration baseline; refine reporting, dispatch and subsequent workflows.

What was delivered

I contributed to platform delivery in four months within a five-person team, against an initial CTO staffing estimate of 22 people for comparable scope. The project record includes Android build handoffs, operator guides, test instructions and workflow revisions.

Before a planned demonstration, I requested a return to a known-working build while keeping newer changes available for later iteration. This kept demonstration readiness separate from subsequent product iteration.

Keep each stage visible

Release records distinguish active builds, inactive candidates and demonstration packages. Hardware checks and human acceptance were tracked separately from automated or simulated verification.

This distinction guided the next step: a build can be ready for a scoped check while the wider service continues through hardware testing, operator feedback and acceptance.

WHAT THIS WORK SHOWS

One thread from need to delivery.

I can independently advance a defined product scope: clarify business needs, shape interactions, review AI-assisted proposals and set priorities and acceptance checks. Carrying that context across stages can help a small team spend less time repeating handoffs and move towards a verifiable delivery with engineering colleagues.

Ongoing company project. Diagrams are anonymised reconstructions; confidential commercial details are omitted.
